The Metonic and Saros Dials

Proposed Reconstruction

Freeth, 2014: Figure 9

The Zig-Zag Model

Based on Babylonian System B

The model has the fixed parameters of :

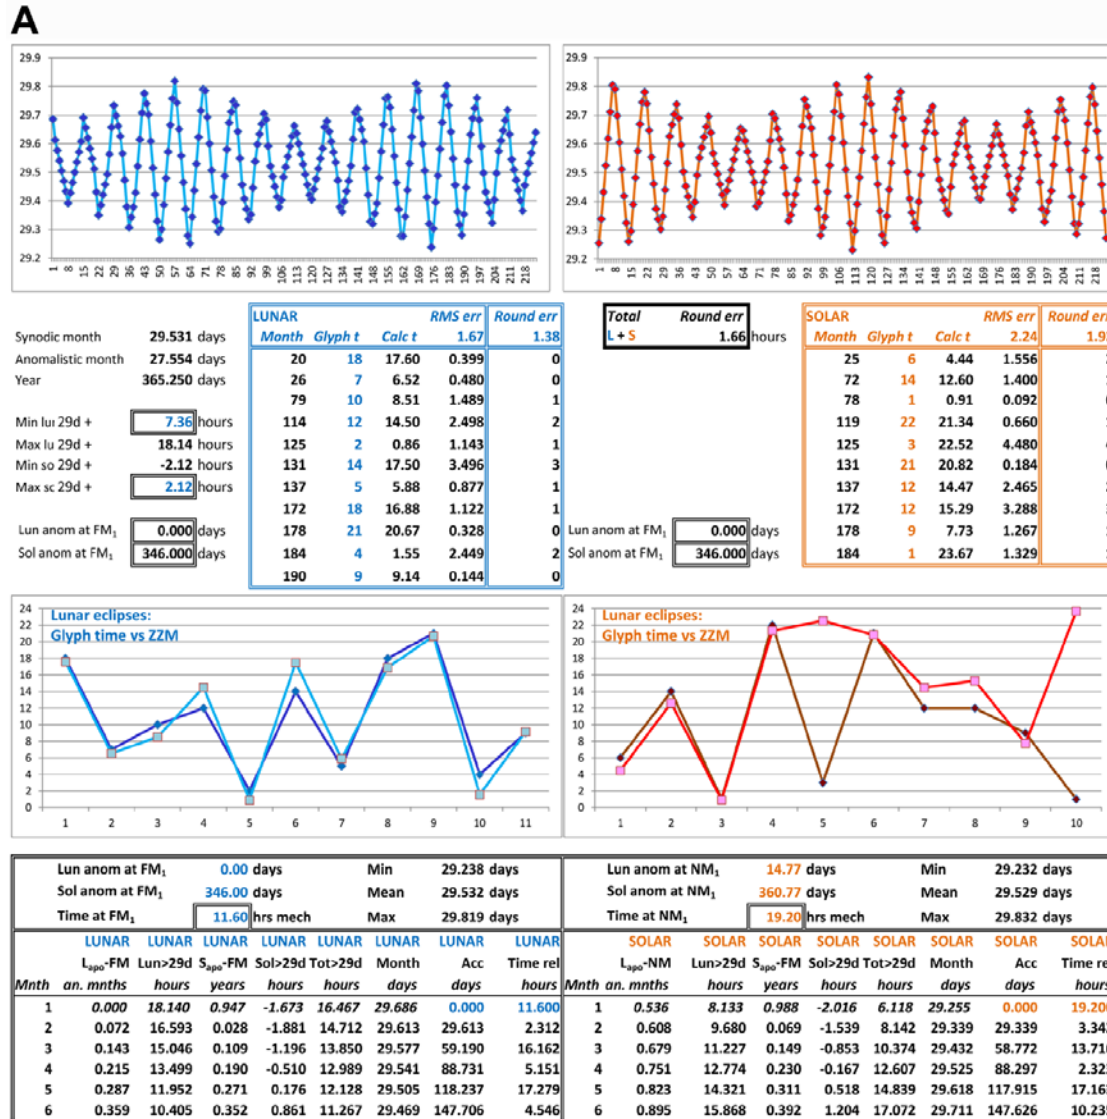

- The Period of the synodic month, $p_{syn} = 29.531$ days
- The Period of the anomalistic month, $p_{anom} = 27.554$ days
- The Period of the solar year, $p_y = 365.25$ days

The parameters tied to astronomy provide the minima and maxima of the functions.

- Min lunar month length – 29.27 days
- Mean = 29.53 days
- Max = 29.82 days

And then free parameters, the phases of lunar and solar anomalies at the astronomical reference point, and the times of the first full and new moons, which are chosen to create the best possible fit between model and glyph times.

- Lunar Anomaly = Number of days $L_{apo} \rightarrow FM_1$
- Solar Anomaly = Number of days $S_{apo} \rightarrow FM_1$
- Time of FM_1
- Time of NM_1

Some questions:

Freeth largely approaches the Antikythera mechanism as a system rather than an artifact. At the same time however, he relies heavily on a classical approach to archaeology. What is the value of this interdisciplinary approach to an archaeoastronomical problem, and do you see any problems in its execution?

Did you find the article to be accessible to the multiple fields of study it might draw interest in? What are some pros and cons of the article's structure?

Are you convinced by Freeth's arguments, and what further steps does his approach require in order to establish a greater degree of certainty?
